

## CHAPTER 4

### METHODS

#### 4.1 Introduction

One of the objectives of this study is to propose a revised methodology on analysing large vegetation data sets. The methodology is also directly in accordance with the primary goals of this study, which includes an attempt to classify the vegetation of the southern African Mopaneveld.

A step-by-step outlay of the procedures is presented as they were tested upon a large database, which includes all adequate vegetation data from the southern African Mopaneveld. The procedures for proposing the new method however involve many other facets of a vegetation study as well. Procedures for treating some of these facets are presented (4.2), followed by the actual procedures for vegetation analysis presented in a step-by-step approach (4.3).

In addition to the synthesis of the entire Mopaneveld, a further synthesis was undertaken on the South African Lowveld Mopaneveld due to special interest in the area and due to adequate vegetation data available from the area. The methods for the synthesis of the South African Lowveld Mopaneveld follow the same procedures as for the synthesis of the entire Mopaneveld. Only the differences in the approach are discussed in this chapter.

Please note that all names of taxa follow Arnold & De Wet (1993). A list of all taxa included in the TURBOVEG database is presented in Appendix 3.

#### 4.2 Steps preceding computer-based procedures

##### 4.2.1 Study area selection

As to propose a method for treating large vegetation data sets, not only was a study area selected according to the availability of phytosociological data, but also according to the contribution

such a study would make to vegetation knowledge of that area. The Mopaneveld of southern Africa was selected as the study area. The selection was motivated by the lack of comprehensive phytosociological knowledge of this extensive vegetation type in spite of relevé data available from several local studies (Chapter 2).

#### 4.2.2 Literature surveying

This dissertation includes an extensive literature survey. Literature on Mopaneveld, including vegetation descriptions, management recommendations, taxonomy, ecology and plant uses were collected. The main function of the literature assessment was to become familiar with the field of study and to present a brief overview on the species *Colophospermum mopane* and on Mopaneveld vegetation over its entire distribution range (Literature Review presented in Chapter 2).

#### 4.2.3 Vegetation data surveying

Applicable and suitable data sets on Mopaneveld vegetation are limited and not freely accessible. A search on vegetation data from studies conducted in any part of the Mopaneveld was undertaken for possible contribution to vegetation classification. Since the study is based on existing data of Mopaneveld vegetation, only a few field surveys were made to complement the existing data.

For existing vegetation data sets to be included in the computer database of Mopaneveld vegetation, the data had to conform to specific criteria as indicated below (4.2.3.1).

##### 4.2.3.1 Criteria for vegetation data inclusion

Data could only be included for analysis if it conformed to the following criteria:

1. Vegetation data had to be sampled in Mopaneveld savanna.
2. Vegetation data had to consist of total floristic composition (therefore including a detailed survey of the woody- and herbaceous strata).

3. Published data with vegetation descriptions should preferably be used, although unpublished data from M.Sc.- or Ph.D studies were also included. Studies undertaken for the fulfilment of lower degrees were only used if the data set could contribute to a relatively undersampled- or an unknown area and after the data were assessed thoroughly for corrections and comprehensiveness.
4. Unpublished data from studies still in progress were included (with agreement with the recorders), especially where the study could contribute to an area where no other adequate vegetation data sets exist.

Adequate habitat data of each vegetation sample should have been a criterion but due to a general lack of habitat data in most of the conducted studies, this criterion could not be included. Suitable, compatible data from the Mopaneveld that conformed to the above criteria were obtained from 15 vegetation studies, listed in Table 2. These were the only compatible phytosociological data available at time of data acquisition.

#### **4.3 Computer-based procedures**

##### **Step 1**

Data sets that conformed to the above criteria were selected and consequently used to compile a database on Mopaneveld vegetation. The database was created in the computer program TURBOVEG (Hennekens 1996a) and is currently stored at the University of Pretoria, Botany Department, African Vegetation and Plant Diversity Research Centre.

Data were captured in the following ways, depending on the format in which data were accessible:

- imported from CEP-files stored in the University of Pretoria main frame database
- captured from field sheets
- captured from published tables
- directly retrieved from existing TURBOVEG files

## Step 2

The complete Mopaneveld database (2 298 relevés stored in TURBOVEG) was exported as a Cornell Condensed species file (cc-file) to a working directory in MEGATAB (Hennekens 1996b). The option in TURBOVEG to distinguish between different vegetation layers a single species occupy, was made inapplicable by combining all layers into one (no layer).

### 4.3.1 Classification

## Step 3

The cc-file was opened in MEGATAB. The option in MEGATAB to change the order of the table was applied using Two-Way-Indicator-Species-Analysis (TWINSPAN) (Hill 1979b). In order to identify relevés representing azonal vegetation, TWINSPAN was applied on a single division level (default cutlevels). After each separation of the table in two parts, the azonal relevés were exported as a cc-file and saved for further analysis in future. This procedure was repeated until the separation revealed two parts containing zonal vegetation in Mopaneveld. A total of 2 246 relevés remained as relevés probably representing zonal vegetation in Mopaneveld.

## Step 4

Due to the inconsistency between authors considering species identification (especially lower than the species level), most subspecies and variations were combined into the relevant species name. This option was carried out in MEGATAB.

## Step 5

TWINSPAN classification was applied to the 2 246 zonal relevés on cutlevels 0-5-25-50 and on 6 levels of division. The rest of the parameters were left default. TWINSPAN revealed the identification of 43 clusters.

## Step 6

The 43 clusters contained various numbers of relevés. Clusters containing less than 5 relevés were omitted from the TWINSPAN table for refinement purposes. During the identification of large vegetation units for the phytosociological synthesis, clusters containing small numbers of relevés were considered not being clearly representative of a large vegetation unit and were

therefore ignored for refinement. After refinement, those clusters were examined and if they contained valuable contributions to the table, they were moved into a suitable position in the table. A total of 29 clusters were considered for refinement.

#### Step 7

To facilitate the immense task of refining a phytosociological table containing more than 2 000 relevés and almost 1 500 species, a synoptic table was constructed directly from the TWINSPAN table as an option in MEGATAB.

#### 4.3.2 Refinement procedures

##### Step 8

1. The order of the species in the synoptic table was changed according to the frequency values of species in each cluster. Species fidelity was not calculated statistically (e.g. Chytrý *et al.* in press). However, all species being more-or-less confined to the same cluster were selected and concurrently moved to the top. These species were then sorted on order of the highest frequency to lowest frequency. All clusters were separately examined for fidelity and frequency after which they were moved into positions where they would compliment diagnostic species groups in the TWINSPAN table.
2. Many species have a wider distribution range, not being confined to only one cluster (i.e. differential species). After diagnostic species groups were identified according to step 8, differential species groups were identified according to high frequency values being shared by different clusters. These species groups were moved into positions where they are most likely to represent relations between clusters (Table 3).

After refinement, the synoptic table was closed. Changes to the order of species in the synoptic table were directly saved to the TWINSPAN table (a very valuable option in MEGATAB). It would however be impractical to present the full table as explanation to the results. Results of the large data set were best expressed in the synoptic table. Although the synoptic table contained only 29 clusters, the number of species still resulted in a very long table (a total of 105 species groups in Table 3!).

### Step 9

Vegetation types and major plant communities within the Mopaneveld were identified according to the synoptic table (Table 3) and relevant habitat information. A vegetation type is suggested to represent a superior plant community containing different major plant communities. Diagnostic species groups for a vegetation type were moved to the top position, followed by its lower-rank diagnostic species groups.

### Step 10

The hierarchy of the TWINSPAN classification was examined in MEGATAB. A dendrogram following TWINSPAN classification was created to present probable explanation of the results (Figure 12).

### Step 11

The synoptic table, containing 29 clusters and 1 465 species, were further reduced to 10 clusters and 329 species (Table 4). Each major vegetation unit (vegetation types and major plant communities) was reduced to a single cluster, in which the frequency of each species to the major plant community or vegetation type was summarised. Frequency values for the larger vegetation units were calculated as follow:

- Each species was treated separately
- Example: *Cyathula uncinulata* (Species group 1, Table 3)
- $x$  = vegetation type/major plant community

$x_1$  would be the very first major plant community/vegetation type (i.e. Zimbabwean Mopaneveld, vegetation type 1, major plant community 1.1 (Table 3))

$x_2$  would be the second major plant community/vegetation type (i.e. Zimbabwean Mopaneveld, vegetation type 1, major plant community 1.2 (Table 3))

- $r$  = number of relevés

$r_a$  would be the total number of relevés in cluster a (Table 3)

$r_{(x1)}$  would be the total number of relevés in the first vegetation type/major plant community

e.g.  $r_{(x1)}$  = total number of relevés in 1.1 (Table 3)

$$= r_a + r_b + r_c + r_d$$

$$= 11 + 17 + 30 + 13 = 71$$

- $y$  = % frequency of plant species

- $y_1$  = % frequency of plant species 1  
 $y_{1a}$  would be the frequency of plant species 1 in cluster a  
e.g. consider *Cyathula uncinulata* species 1  
 $y_{1a} = 18$   
 $y_{1b} = 35$  etc.
- $r_{a1}$  = number of relevés in which species 1 occur in cluster a  
 $= y_{1a}/100 \times r_a$   
 $= 18/100 \times 11$   
 $= 1.98$   
 $\sim 2$  relevés
- $y_{1(x1)}$  = % frequency of species one (e.g. *Cyathula uncinulata*) in major plant community/vegetation type 1  
 $y_{1(x1)} = r_{a1} + r_{b1} + r_{c1} + r_{d1} / r_{(x1)}$   
 $= 2+6+30+12 / 71$   
 $= 50/71 \times 100$   
 $= 70\%$  (Table 4)

The above calculations reduced the synoptic table in terms of clusters representing major vegetation units, although the number of species in the table remained high. In order to decrease the number of species to present a short, yet valuable expression of the major vegetation units in the Mopaneveld of southern Africa, species were selected according to their fidelity to, and their frequency in the vegetation unit they occur in. Species of frequency lower than 10 % in a syncluster (e.g. *Hermstaedtia linearis* in Species group 3, Table 4) were not selected for the reduced table (Table 5) although it is 18 % frequent in cluster b in Table 3. This selection and elimination of species resulted in a 10 cluster synoptic table containing 329 species being representative of the major vegetation units in the Mopaneveld being studied (Table 5).

### Step 12

This reduced synoptic table (Table 5) was used to describe the vegetation types and major plant communities within the study area. Diagnostic species for each vegetation type and major plant community were identified according to their fidelity. Species being diagnostic for two and more vegetation units were regarded indicators of similarity between vegetation units.

#### 4.3.3 Ordination

Species composition may be a more informative indicator of environment than any set of measured environmental variables (Ter Braak 1995). Considering the importance of environmental conditions on the distribution of Mopaneveld vegetation types, the ordination algorithm DECORANA (Detrended Correspondence Analysis) (Hill 1979a) was applied to the floristic data to relate the distribution of the major types along environmental gradients. The ordination algorithm was applied to the synrelevés rather than to all 2 246 relevés, due to the enormous dimensions of the data set.

The synoptic table created in MEGATAB was exported as a Cornell Condensed Species File. DECORANA was then applied to the exported synrelevés. No transformation of the data was carried out and all parameters were set to defaults during the application of DECORANA to the 29 clusters (synrelevés). A scatter diagram was created to present DECORANA results (Figure 19). Habitat data for each cluster were traced from the published literature and accordingly environmental gradients were fitted to the diagram.

### 4.4 Synthesis of the South African Lowveld Mopaneveld

For the synthesis of the South African Lowveld Mopaneveld, results of the complete synthesis of the southern African Mopaneveld were needed. After the South African Lowveld Mopaneveld (SALM) was identified as the *Cissus cornifolia* - *Colophospermum mopane* major vegetation type, all relevés representing this vegetation type were exported as a cc-file to a separate working directory in MEGATAB. The data of the SALM were therefore presented in a raw data matrix prior to further analysis. All procedures for the synthesis of the SALM were undertaken in that directory. Since the SALM vegetation data comprises more than 1 000 relevés itself, it was thought useful to apply the same method for data analysis (4.3) as was proposed for the analysis of the data set containing data from 15 studies undertaken in the Mopaneveld.

TWINSPAN classification was applied to the 1 375 relevés, firstly on a single division level. Since the scale in this part of the study narrowed, it was necessary to identify and discard all relevés representing azonal vegetation. The Sandveld communities of the Punda Milia-Pafuri-

Wambiya (Van Rooyen 1981b) were thought to be clearly separated by this procedure. However, many relevés representing those communities remained within the scope of Mopaneveld vegetation. After a division within the Mopaneveld resulted, TWINSPAN was applied to the remaining relevés on default cutlevels and default levels of division. A synoptic table was constructed in order to identify the major plant communities within the SALM. The same procedures were followed as in *Step 11* to present a reduced synoptic table of the four major plant communities of the SALM (Table 6).

The procedures following the identification of the major plant communities in the SALM differ somewhat from the entire synthesis. Four major plant communities were identified and were further analysed separately to identify the plant communities within each. Each major plant community was therefore exported as a separate file for further analysis. TWINSPAN classification at default cutlevels and two levels of division were regarded the most effective procedure in which plant communities, which probably represent alliances, could be identified for each of the four major plant communities. Since the study did not aim to identify plant communities below the alliance level, only several relevés in “oversampled” areas (regarded oversampled only for the purpose of this study) were included in the final tables. The relevés to be included in the final tables were selected randomly within each cluster for the results to be easily presented in Braun-Blanquet tables (Tables 7 & 8).

Refinement procedures followed the Braun-Blanquet approach (Westhoff & Van der Maarel 1982), which were proved to be successful in several phytosociological studies (e.g. Behr & Bredenkamp 1988; Dekker & Van Rooyen 1995; Brown 1997; Eckhardt *et al.* 1996; Visser *et al.* 1996; Smit *et al.* 1997). The phytosociological tables contain total floristic composition of the major plant communities. Species abundance is presented at the Braun-Blanquet cover-abundance scale.

The discussion on two of the four major plant communities within the SALM is presented in Chapter 6. Although analysis and refinement of all four major plant communities have been completed, only two are included in this study because the description actually falls beyond the objectives of this study. The complete synthesis of the SALM will however be presented in subsequent papers.

Table 2 Data sets used for a phytosociological synthesis on Mopaneveld vegetation

Author	Year	Location	No. of Relevés
1. Beck, N.G.	1998	Foskor, mine, Phalaborwa, South Africa	114
